CY7C185

Features

- High speed
 15 ns
- Fast t_{DOE}
- Low active power
 - —715 mW
- Low standby power — 220 mW
- CMOS for optimum speed/power
- Easy memory expansion with \overline{CE}_1 , CE_2 and \overline{OE} features
- TTL-compatible inputs and outputs
- Automatic power-down when deselected

Functional Description

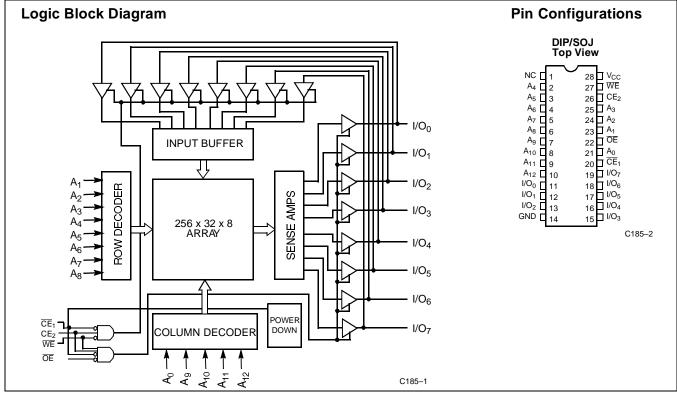

The CY7C185 is a high-performance CMOS static RAM organized as 8192 words by 8 bits. Easy memory expansion is

8K x 8 Static RAM

provided by an active LOW chip enable (\overline{CE}_1), an active HIGH chip enable (CE_2), and active LOW output enable (\overline{OE}) and three-state drivers. This device has an automatic power-down feature (\overline{CE}_1 or CE_2), reducing the power consumption by 70% when deselected. The CY7C185 is in a standard 300-mil-wide DIP and SOJ package.

An active LOW write enable signal (\overline{WE}) controls the writing/reading operation of the memory. When \overline{CE}_1 and \overline{WE} inputs are both LOW and CE_2 is HIGH, data on the eight data input/output pins (I/O₀ through I/O₇) is written into the memory location addressed by the address present on the address pins (A₀ through A₁₂). Reading the device is accomplished by selecting the device and enabling the outputs, \overline{CE}_1 and \overline{OE} active LOW, CE_2 active HIGH, while \overline{WE} remains inactive or HIGH. Under these conditions, the contents of the location addressed by the information on address pins are present on the eight data input/output pins.

The input/output pins remain in a high-impedance state unless the chip is selected, outputs are enabled, and write enable $(\overline{\text{WE}})$ is HIGH. A die coat is used to insure alpha immunity.

Shaded areas contain preliminary information.

Notes:

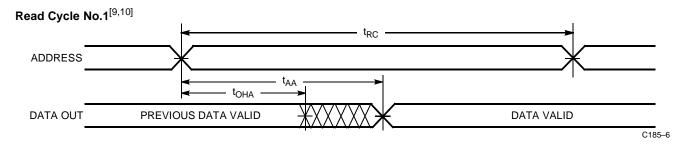

5.

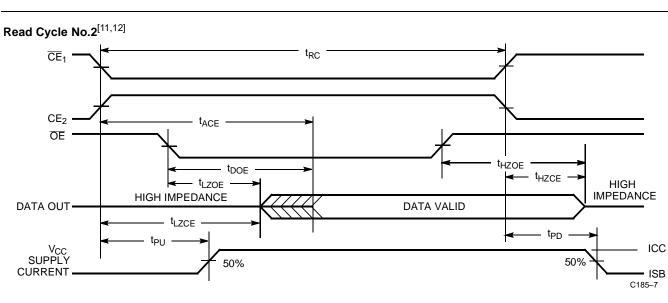

6. 7. 8.

Test conditions assume signal transition time of 5 ns or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, and output loading of the specified J_{0L}/I_{0H} and 30-pF load capacitance. t_{HZOE} , t_{HZCE} , and t_{HZWE} are specified with $C_L = 5$ pF as in part (b) of AC Test Loads. Transition is measured ±500 mV from steady state voltage. At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE} and t_{LZCE} ? for any given device. The internal write time of the memory is defined by the overlap of CE_1 LOW, CE_2 HIGH, and WE LOW. All 3 signals must be active to initiate a write and either signal can terminate a write by going HIGH. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write.

Switching Waveforms (continued)

Write Cycle no.2 (CE Controlled)^[12,13,15]

Write Cycle No.3 (WE Controlled, OE LOW)^[12,13,14,15]

Notes:

- 9. 10.
- 11.

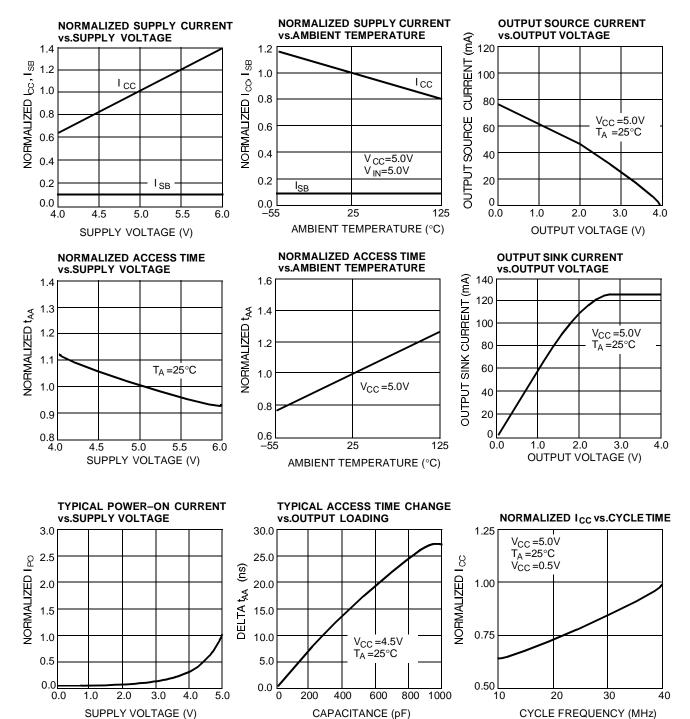

The minimum write cycle time for write cycle #3 (WE controlled, \overline{OE} , $\overline{CE}_1 = V_{IL}$, $CE_2 = V_{IH}$. The minimum write cycle time of the memory is defined by the overlap of \overline{CE}_1 LOW, CE_2 HIGH and \overline{WE} LOW. \overline{CE}_1 and \overline{WE} must be LOW and CE_2 must be HIGH to initiate write. A write can be terminated by \overline{CE}_1 or WE going HIGH or CE_2 going LOW. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write. The minimum write cycle time for write cycle #3 (WE controlled, \overline{OE} LOW) is the sum of t_{HZWE} and t_{SD} . If \overline{CE}_1 goes HIGH or CE_2 goes LOW simultaneously with WE HIGH, the output remains in a high-impedance state. During this period, the I/Os are in the output state and input signals should not be applied. 12.
